The KScr Language

Definition of the KScr Language

comroid

The KScr Language as defined by this document is a compiled high-level language whose goal is to provide runtime optimizations from a different approach.

<u>Team:</u> Kaleidox

1 Source Model

1.1 Modifiers

1.1.1 Accessibility Modifiers

Modifier	Function
public	Accessible from everywhere
internal	Accessible during compilation; compiled to private
protected	Accessible from inheritors
private	Accessible from inside only

1.1.2 Other Modifiers

Modifier	Function
static	Cannot be invoked dynamically
final	Cannot be overridden or changed
abstract	Must be implemented in inheritors
synchronized	Invocations are synchronized
native	Must be implemented by a native module

1.2 Classes

1.2.1 Class Types

A source class can be of different types:

1.2.1.1 class-Type A normal class that can be instantiated. Allowed modifiers are:

Modifier	Function
static	Cannot be instantiated and behaves like a Singleton
final	Cannot be inherited by other classes
abstract	Cannot be instantiated directly and must be inherited by other classes

- **1.2.1.2 enum-Type** An enumeration of runtime-constants that follow a class-like pattern. This type does not allow modifiers.
- 1.2.1.3 interface-Type An interface that declares basic structure requirements for implementing classes. Cannot be instantiated directly.

1.2.1.4 annotation-Type

KScr Language

1.2.2 Type Generics

1.3 Class Members

1.3.1 Static Initializer

1.3.2 Constructors

1.3.3 Methods

1.3.4 Properties

2 The KScr VM

2.1 Built-in Types

2.1.1 interface void

The universal base type. Is implemented by all built-in types and can be implicitly cast to everything.

2.1.2 class num<T>

The base type of all numerics. Contains numeric subtypes:

- 1. byte Type-alias for int<8>
- 2. short Type-alias for int<16>
- 3. int < n = 32 >
- 4. long Type-alias for int<64>
- 5. float
- 6. double

All subtypes can be used directly, or using the Type Generic T, for example: int<24> == num<int<24>

- 2.1.3 class str
- 2.1.4 class object
- 2.1.5 class array<T>
- 2.1.6 class tuple<T...>
- 2.1.7 class enum<T>
- 2.1.8 class type<T>
- 2.1.9 class pipe<T...>
- 2.2 Literals
- 2.2.1 null

The null-Literal. Is always of type void.

2.2.2 Numeric Literals

2.2.3 String Literals

A string literal is pre- and superceded by a double-quote " symbol. An escaped double-quote $\$ " can be contained in the string.

2.2.3.1 Planned Behaviour: Interpolation A string supports interpolation using accolades with Formatter-support with the following syntax:

```
int hex = 1 << 3;
stdio <<- "hex: {hex:X}"
// prints "hex: 0x4"</pre>
```

2.2.4 Array Literals

Unimplemented.

2.2.5 Tuple Literals

Unimplemented.

2.2.6 Other Literals

2.2.6.1 stdio Constantly represents the program's standard IO stream. The held value is of type pipe<str>
